Introduction to relational databases

INFO/CS 2300: Intermediate Web Design and Programming

Course overview

We started with PHP

Then JavaScript

Ajax: the client / browser JS side if it

The next few weeks - databases and SQL

Homework 1: Using JavaScript / jQuery

We give you HTML and CSS for a page. You write the JavaScript / jQuery to make modifications

Posted on Piazza.

Due Tuesday February 28 at 5 pm.

Friday Section

Quiz is on last week's lecture material, not today's.

Activity is also JavaScript not databases

P2: Limitations of file storage

What was difficult about storing data in a text file?

What challenges would emerge if you tried to store thousands of items?

P2: Limitations of file storage

List from lecture

- Easy to corrupt
- it's hard to find one thing amidst all that text data
- it's a pain to find help online because no one does this with text files
- You can end up with copies of large text files
- You have to update the whole file every time you update a piece of it

P2: Limitations of file storage

Steve's list

- write the whole file to edit / delete
- Hold file in memory or frequent read/write
- Managing delimiters
- Enforcing data types
- Find requires looping through whole file
- Requiring that an item belong to a list
- multi-user

Rollercoasters

Roller coaster	Type	Park	# of rides	Increment
Top Thrill Dragster	Steel	Cedar Point	1	Increment
El Toro	Wood	Six Flags Great Adventure	2	Increment
Leviathan	Steel	Canada's Wonderland	1	Increment
Intimidator 305	Steel	Kings Dominion	7	Increment
Mean Streak	Wood	Cedar Point	1	Increment
	Wood ▼			Add new

The data in the table is a database. But there are limitations when storing data in a text file.

- Type options are hard coded in the HTML
- Inefficient: have to rewrite the file to increment rides
- delimiters are a nuisance

Relational databases

What is...?

A database is a collection of related data.

A database management system (DBMS, database system) is software used to manage a database efficiently.

A DBMS...

- Allows for persistent storage of very large amounts of information, and efficient access to it.
- Implements a "query language" (SQL) to store, access, and modify the data.
- Can enforce that the stored data is consistent in certain ways.
- Manages access by many users.

Imagine we have functions...

- update_ride_count(\$coaster)
- add_coaster(\$name, \$type, \$park)
- get_coasters_sorted_by(\$column)
- get_coasters_where(\$search)

Now package up those functions so that they can be used by code we write for our website.

We could call it a Coaster Management System But a Database Management System is better

A running example: Movies

Fields associated with a movie:

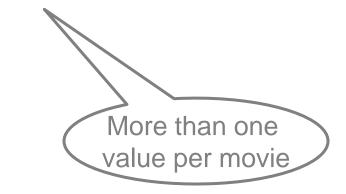

A running example: Movies

Fields associated with a movie:

- year
- director
- title
- genre
- rating
- length

•

actor / actress

Why "relational"?

The data is organized in *relations* (or *tables*).

The columns are called attributes or fields.

The rows are called *tuples* or *records*. Each row must be unique.

Each column / field has a set of allowable values called its

domain for year is 4 digit integer

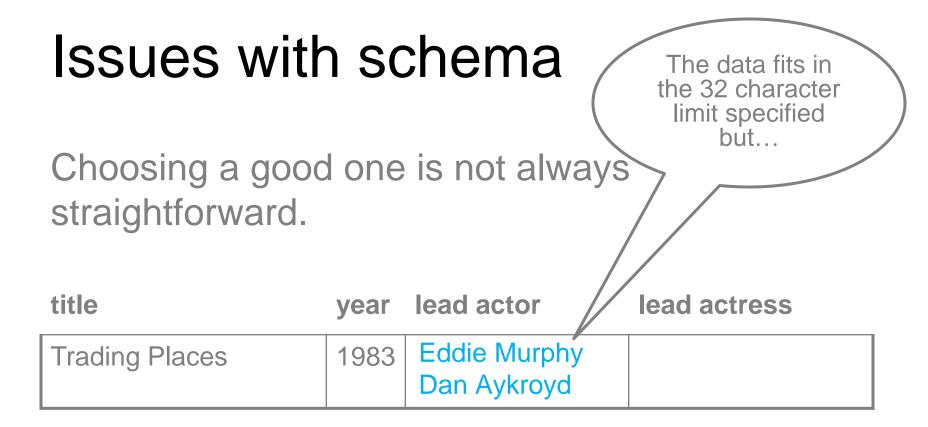

domain.

title	year	lead actor	lead actress
Sleepless in Seattle	1993	Tom Hanks	Meg Ryan
Holiday	1938	Cary Grant	Katherine Hepburn
The Princess Bride	1987	Cary Elwes	Robin Wright

Table schema

The table schema is a named set of attributes (fields) together with their associated domains (allowed values).

Field (attribute)	Туре	Size	Allow null
title	VARCHAR	64	No
year	INT		No
lead_actor	VARCHAR	32	Yes
lead_actress	VARCHAR	32	Yes

Your instinct should be "something isn't right."

Constraining the data

Unique rows

A table must have uniquely identifiable rows (records) title year length

Harry Potter and the Sorcerer's Stone	2001	152
The Dark Knight	2008	152
Planet of the Apes	1968	112
Planet of the Apes	2001	119
Planet 51	2009	91

How would we naturally talk about a record in this table?

Primary Key

A *primary key* is the field(s) selected to uniquely identify records in the table.

title	year	length
Harry Potter and the Sorcerer's Stone	2001	152
The Dark Knight	2008	152
Planet of the Apes	1968	112
Planet of the Apes	2001	119
Planet 51	2009	91

Primary Key: Natural vs Surrogate

A natural key is made up of fields (attributes) that exist in the real world. (title, year)

A surrogate key adds an artificial field (movie_id)

movie_id	title	year	length
1	Harry Potter and the Sorcerer's Stone	2001	152
2	The Dark Knight	2008	152
3	Planet of the Apes	1968	112
4	Planet of the Apes	2001	119
5	Planet 51	2009	91

Sometimes fields appear in more than one table, implying a relationship between the two.

title	year	length
Moonlight	2016	111
Holiday	1938	95 mins.
The Philadelphia Story	1940	112 mins.
Sabrina	1954	113 mins.
Planet of the Apes	1968	112
Planet of the Apes	2001	119

name	year	title
Moonlight	2016	Mahershala Ali
Katherine Hepburn	1938	Holiday
Katherine Hepburn	1940	The Philadelphia Story
James Stewart	1940	The Philadelphia Story
Charlton Heston	1968	Planet of the Apes
Charlton Heston	2001	Planet of the Apes

The same tables with a surrogate key for the movie table

movie_id	title	year	length

o		your	10119111
1	Moonlight	2016	111
2	Holiday	1938	95
3	The Philadelphia Story	1940	112
4	Planet of the Apes	1968	112
5	Planet of the Apes	2001	119

name movie_id

(primary key

Tidillo	1110 110_16
Mahershala Ali	1
Katherine Hepburn	2
Katherine Hepburn	3
James Stewart	3
Charlton Heston	4
Charlton Heston	5

Primary Key: Natural vs Surrogate

Natural Key

Surrogate Key

title, year	movie_id
Disadvantage: it can be cumbersome to work with multiple fields	Advantage: only one field needed
Advantage: meaning to humans	Disadvantage: no inherent meaning to humans
Disadvantage: If business rules change, key must too	Advantage: remains independent of business rules

Nulls: a special case

Sometimes have "null" – i.e. no value -- for a field. Null can mean one of two things:

1. There should be a value, but we don't know what it is.

Title	Year	Length
Metropolis	1927	Null

2. There isn't a value for this particular record.

Title	Year	Lead actor	Lead actress
20,000 Leagues Under The Sea	1954	Kirk Douglas	Null

Entity integrity

Primary keys cannot have null fields. Why?

Null isn't a value. It carries a meaning that is different from having a value.

Its against the rules.

Foreign keys

If a field is (or fields are) a primary key in another table, we call this a *foreign key*. It refers to or targets the other table.

movie_id	title	year	length
1	Moonlight	2016	111
2	Holiday	1938	95
3	The Philadelphia Story	1940	112
4	Planet of the Apes	1968	112
5	Planet of the Apes	2001	119

name	movie_id
Mahershala Ali	1
Katherine Hepburn	2
Katherine Hepburn	3
James Stewart	3
Charlton Heston	4
Charlton Heston	5

Why foreign keys?

Why might foreign keys be interesting?

movie_id	title	year	length
2	Holiday	1938	95
3	The Philadelphia Story	1940	112
4	Planet of the Apes	1968	112
5	Planet of the Apes	2001	119

name	movie_id
Katherine	2
Hepburn	
Katherine	3
Hepburn	
James Stewart	3
Charlton Heston	4
Charlton Heston	5

What is the average length of a Katherine Hepburn movie?

Why else foreign keys?

movie_id	title	year	length
2	Holiday	1938	95
3	The Philadelphia Story	1940	112
4	Planet of the Apes	1968	112
5	Planet of the Apes	2001	119

name	movie_id
Katherine Hepburn	2
Katherine Hepburn	3
James Stewart	3
Charlton Heston	4
Charlton Heston	5

Can impose constraints such as preventing "Holiday" from being deleted from the Movie table or insisting that an actor's movie exist in the movie list.

Referential integrity

If a foreign key exists in a table, either it must match the primary key a record in the related table or the foreign key value must be null. No bogus references allowed.

If the foreign key is also constrained to be not null, then no orphan records.

Referential integrity

movie_id	title	year	length
1	Sleepless in Seattle	1993	105
2	Holiday	1938	95
3	The Philadelphia Story	1940	112
4	Sabrina	1954	113

name	movie_id
Katherine Hepburn	2
Katherine Hepburn	3
James Stewart	3

With a constraint set, Holiday 1938 can only be deleted from the movie table if there is no reference to it in the StarsIn table. Katherine Hepburn's "2" prevents this. Depending on the rules this could be handled with null, delete or cascade delete.

General constraints

Can add other types of constraints to make sure the data has integrity.

E.g.

- date
- integer
- float

Specifying schema

We often write down the schema for a relational database as follows:

```
Movies (<u>Title</u>, <u>Year</u>, Length)
StarsIn (<u>Name</u>, <u>Title</u>, <u>Year</u>)
```

where the underline indicates the primary key of the relation.

Sometimes we add domain information: Movies (<u>Title: string</u>, <u>Year: integer</u>, Length: integer)

Click In...

A _____ uniquely defines a record in a table.

- 1. Primary key
- 2. Surrogate key
- 3. Natural key
- 4. All of the above
- 5. Foreign key

- A _____ uniquely defines a record in a table.
- 1. Primary key
- 2. Surrogate key
- 3. Natural key
- 4. All of the above
- 5. Foreign key

Surrogate and Natural keys are each a type of Primary key

- Consider a rollercoaster DB schema: Coaster(Name, Park, Type, Year). What is a good primary key?
- A. Name
- B. Park, Year
- C. Name, Park
- D. Name, Type
- E. Name, Year

Consider a rollercoaster DB schema: Coaster(Name, Park, Type, Year). What is a good primary key?

A. Name

B. Park, Year

C. Name, Park

D. Name, Type

E. Name, Year

Best answer: High likelihood of uniqueness

Depending on assumptions about the data, all other answers could be correct

```
Movies (movie_id, title, year, length)
StarsIn (name, movie_id)
```

The foreign key in this schema is:

- A. movie_id in Movies
- B. movie_id in StarsIn
- C. name and movie_id in StarsIn
- D. title and year in Movies
- E. None of the above.

```
Movies (movie_id, title, year, length)
StarsIn (name, movie_id)
```

The foreign key in this schema is:

- A. movie_id in Movies
- B. movie_id in StarsIn
- C. name and movie_id in StarsIn
- D. title and year in Movies
- E. None of the above.

Now you try...

Course registration

Suppose you are putting together a database that allows students to register for courses each semester. Give a sample relational database schema for this database.

What tables are needed?

What fields belong in each table?

What are the primary keys for each table?

What are foreign keys?

One possible solution

Tables

Students

Courses

Registrations

Tables, fields

Students(netid, first_name, last_name)
Courses(dept, number, time, semester)
Registrations(netid, dept, number, semester)

Students(netid, first_name, last_name)
Courses(course_id, dept, number, time, semester)
Registrations(netid, course_id)

Could also add registration_id

Tables, fields, primary

Students(<u>netid</u>, first_name, last_name)
Courses(<u>dept</u>, <u>number</u>, time, <u>semester</u>)
Registrations(<u>netid</u>, <u>dept</u>, <u>number</u>, <u>semester</u>)

Students(<u>netid</u>, first_name, last_name)
Courses(<u>course_id</u>, dept, number, time, semester)
Registrations(<u>netid</u>, <u>course_id</u>)

Or: Registrations(<u>registration_id</u>, netid, course_id)

Tables, fields, primary, foreign

Students(<u>netid</u>, first_name, last_name)

Courses(dept, number, time, semester)

Registrations (netid, dept, number, semester)

Students(<u>netid</u>, first_name, last_name)
Courses(<u>course_id</u>, dept, number, time, semester)
Registrations(<u>netid</u>, <u>course_id</u>)

Or: Registrations(registration_id, netid, course_id)
